Motivation

- In 2022 global fossil fuel prices started to soar upon Russia's invasion of Ukraine.
- The rise in the relative price of fossil resources may weigh on the economy if firms and households cannot substitute more expensive carbon-intensive energy with greener and cheaper alternatives.
- Factors such as sectoral composition and labor market rigidities are likely to matter for the transmission of supply shocks and their persistence.
- Central banks may need to be more aggressive in their responses in economies where workers are less willing to accept real wage declines or where the weight of energy-intensive sector is larger.

This paper

- We develop a multi-sector industry dynamic model to study these issues.
- In our model, a shock to the price of fossil resources affects the relative size of the sectors in the economy through changes in productivity and the entry and exit of heterogeneous firms.
- Monetary policy affects these dynamics through its GE effects on firms' revenues and the real wage.

<ロ > < 母 > < 臣 > < 臣 > < 臣 > ○ < ♡ < ?29

We estimate the model's parameters through a moments matching technique.

Model

Model's key features:

- two final good sectors, which we identify as manufacturing and services, that have ex-ante different energy intensities;
- 2. firms are heterogeneous in terms of productivity and are subject to endogenous entry and exit;
- 3. imperfectly competitive goods and labor markets with nominal rigidities;
- two energy sectors, one producing energy with renewables, the other with dirty inputs;
- 5. the two types of energy are bundled in a final energy product, used both in production and consumption.

<□ > < @ > < E > < E > E のQ (4/29

Preview of results

In the aftermath of an increase in the price of fossil resources our analysis suggests:

- A reallocation of activity from energy-intensive sectors to greener sectors
- An increase in labor productivity, more so in energy-intensive sectors.
- A persistent decrease in the number of active firms through a decrease in the entry rate and an increase in the exit rate.
- A greener production of energy, promoting both a greener production and consumption.

Mechanism

Increase in the price of the fossil resource

∜

Higher marginal costs in both sectors more so in manufacturing, which is energy intensive

∜

Higher idiosyncratic productivity required to enter and survive.

₩

Entry is persistently depressed due to higher productivity requirement

The role of monetary policy

- A monetary policy tightening in response to the fossil price shock generate GE effects that affect productivity through 2 channels:
 - 1. Revenue channel: a higher real rate reduces aggregate demand, which in turn depresses firm revenues \Rightarrow a HIGHER idiosyncratic productivity is required for both survival and market entry.
 - Cost channel: lower demand for final goods reduces the demand for labor, leading to lower labor costs for firms⇒ a LOWER idiosyncratic productivity is required for both survival and market entry.

A stabilization challenge

- The monetary policy stance alters the relative strength of the revenue and cost channels.
- More anti-inflationary policies depress output to a large extent, but also dampen real wages, leading to a milder increase in productivity in both sectors.
- The smaller productivity boost under tighter policies allows the entry rate to recover more rapidly after the shock in both the services and manufacturing sectors.
- Our results therefore reveal a novel trade-off in monetary policy: balancing the stabilization of aggregate activity on one hand and fostering business dynamism on the other.

Production of Goods

- 2 ex-ante heterogeneous sectors: manufacturing, the brown good, and services, the green good.
- Production: Cobb Douglas in labor and energy. Manufacturing is energy-intensive.
- final goods is a CES aggregate of the manufacturing goods and service goods.
- Within each sector: Heterogeneous firms with endogenous entry and exit 'a la Melitz (2003), augmented with nominal rigidities as Colciago and Silvestrini (2022).
- Monopolistic competition.
- Rotemberg (1982) pricing.

Entry and Exit

- Upon entry, firms are assigned a productivity level drawn from a Pareto distribution.
- Firm Entry: if discounted value of future profits is larger than the entry cost, following Bilbiee, Ghironi and Melitz (2012).

◆□▶ ◆□▶ ◆ ■▶ ◆ ■ ▶ ● ■ ● ○ Q ○ 10/29

Firm Exit: if period profits are negative.

Production of Energy

- 2 sectors: Dirty and clean energy.
- Clean energy: Cobb Douglas in labor and renewable resource.
- Dirty energy: Cobb Douglas in labor and fossil resource.
- price of fossil resources is exogenous, supply of renewable is constant.

Definition: the core good

Core good is an aggregate of the two sectorial goods Y_t(g) and Y_t(b), denoting aggregate output in the services (green) and manufacturing (brown) sector, respectively:

$$Y_t^{core} = \left(\chi^{\frac{1}{\eta}} Y_t(g)^{\frac{\eta-1}{\eta}} + (1-\chi)^{\frac{1}{\eta}} Y_t(b)^{\frac{\eta-1}{\eta}}\right)^{\frac{\eta}{\eta-1}}$$
(1)

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへで 12/29

Both Y_t(g) and Y_t(b) are aggregators of goods produced in the green and brown sectors.

Definition: energy

The energy provider bundles clean energy, E_{C,t}, and dirty energy, E_{D,t}, with the following CES production function:

$$E_{t} = \left[\xi^{\frac{1}{\rho}} E_{D,t}^{\frac{\rho-1}{\rho}} + (1-\xi)^{\frac{1}{\rho}} E_{C,t}^{\frac{\rho-1}{\rho}}\right]^{\frac{\rho}{\rho-1}}$$
(2)

▲□▶▲圖▶▲圖▶▲圖▶ 圖 の요@ 13/29

- ρ is the elasticity of substitution between clean and dirty energy, and ξ their relative weight in the input bundle.
- The variable E_t is the quantity of energy produced at time t that is sold to the market.

Definition: final good

The final consumption good is assumed to be a composite between a 'core' good, denoted by Y^{core}_t, and energy, denoted by E^H_t.

$$Y_t = \left(\omega^{\frac{1}{\tilde{\eta}}} (Y_t^{core})^{\frac{\tilde{\eta}-1}{\tilde{\eta}}} + (1-\omega)^{\frac{1}{\tilde{\eta}}} (E_t^H)^{\frac{\tilde{\eta}-1}{\tilde{\eta}}}\right)^{\frac{\eta}{\tilde{\eta}-1}}, \quad (3)$$

▲□▶▲@▶▲≣▶▲≣▶ ≣ の९ペ 14/29

where the parameter ω captures the relative importance of the core good compared to energy in the consumption bundle, and the parameter $\tilde{\eta}$ measures the elasticity of substitution between the two goods.

Demand side

- 1. Households maximize lifetime utility over Consumption and Hours
- 2. Provide differentiated labor inputs. Calvo (1982) nominal wage stickiness.
- 3. Complete markets
- 4. Households can invest in firms through the stock market;
- 5. Households invest in entry up to the point where the entry cost equals the discounted value of future profits.

◆□▶ < @ ▶ < E ▶ < E ▶ ○ Q ○ 15/29</p>

The Central Bank sets the nominal interest rate, R_t , according to the following Taylor rule with smoothing:

$$\left(\frac{R_t}{R}\right) = \left[\left(\frac{\pi_t}{\pi}\right)^{\phi_{\pi}} \left(\frac{Y_t}{Y}\right)^{\phi_{Y}}\right]^{1-\phi_{R}} \left(\frac{R_{t-1}}{R}\right)^{\phi_{R}}, \quad (4)$$

▲□▶ ▲□▶ ▲ ■▶ ▲ ■▶ ■ ⑦ ٩ ℃ 16/29

where variables without time subscript denote steady state values. For simplicity, we assume that the steady state gross inflation rate equals one.

Key mechanism: productivity cutoff

- to enter the market and to continue production, firms must have an idiosyncratic productivity larger than a threshold z^{*}_t
- the latter, under flexible prices, is given by

$$z_t^c(q) = \frac{\theta^{\frac{\theta}{\theta-1}}}{\theta-1} \frac{1}{Z_t(q)} \left(\frac{w_t}{1-\alpha_q}\right)^{1-\alpha_q} \left(\frac{p_t^E}{\alpha_q}\right)^{\alpha_q} \left(\frac{f_{x,t}}{\rho_t(q)^{\theta} Y_t(q)}\right)^{\frac{1}{\theta-1}}$$
(5)

z^{*}_t depends on:

- 1. the real wage, w_t .
- 2. the relative price of energy p_t^E .
- 3. fixed costs of production, f^{fix}
- 4. aggregate production, Y_t^c
- 5. α_q is the parameter on Energy in the CD production function of final good.

Parameterization

- 1. *Calibration*: We calibrate a subset of the model's parameters by relying on empirical data and targets from the literature specific to the US economy.
- 2. *Estimation*: The remaining parameters are estimated by minimizing the difference between twelve unconditional moments derived from US data and their corresponding model-generated moments.
- 3. To compute the model's moments, we introduce three aggregate shocks: to the price of fossil resources, to aggregate technology, and monetary policy.

Calibration

Parameter	Description	Value
Households a	nd wage setting	
β	discount factor	0.98
ϕ	inverse Frisch elasticity	4
X	share of good g in core good bundle	0.7
η	elasticity of substitution between good g and b	1.5
θ_w	elasticity of substitution between labour inputs	4
Firms		
α_g	production share of energy in sector g	0.017
α_b	production share of energy in sector b	0.051

Estimation

The values of the parameters are selected to solve the following minimization problem

$$\min_{\Theta} \left(mom^{DSGE}(\Theta) - mom^{DATA} \right)' \mathbf{W} \left(mom^{DSGE}(\Theta) - mom^{DATA} \right),$$
(6)

where

- 1. $\boldsymbol{\Theta}$ is the column vector that contains the parameters to be estimated
- 2. mom^{DATA} is a column vector containing the empirical moments
- 3. *mom^{DSGE}* is the vector of the corresponding model-implied moments
- 4. we use the identity matrix as the weighting matrix.

Estimated Parameters

Parameter	Description	Value
τ	Rotemberg price setting	159.77

Summary

- We provide a multi-sector industry dynamic model with endogenous entry and exit of heterogeneous firms to analyze the short- to medium-term impact of a persistent increase in the price of fossil resources on:
 - 1. the relative size of sectors;
 - 2. labor productivity;
 - 3. Competitiveness.
- The energy price shock triggers a selection and cleansing process. The latter leads to:
 - 1. higher average productivity in both the manufacturing and service sectors.
 - 2. contraction in business entry
- A central bank with a strong anti-inflationary stance entails a higher impact cost in terms of output and lower average productivity in response to the shock, but a faster recovery of firms creation.
